

1, Explain behaviour of hub device

It is used to connect the multiple device. It is a broadcast device.
 * We have three pc's name as A, B, C port no is A-1, B-2, C-3. First of all the data is sent to port A to port B. Send the data to hub. The data can be broadcast to all pc. Send port and * Main think, once the data is shared to the hub, it can be traffic. The behaviour is once you share the data from one pc to hub, the data can be broadcast

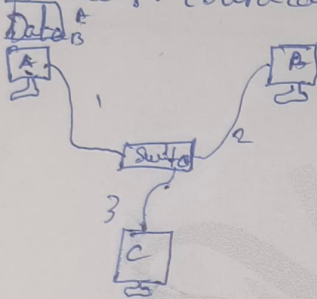

2, Explain behaviour of switch device

connects Device : Link multiple pc using a MAC address

Address Learning: stores port number and MAC address when data is received.

Broadcast to unicast: Broadcast initial data to all pc when destination is unknown, then switches to direct unicast once MAC address are learned.

Broadcast => Switch => Broadcast.

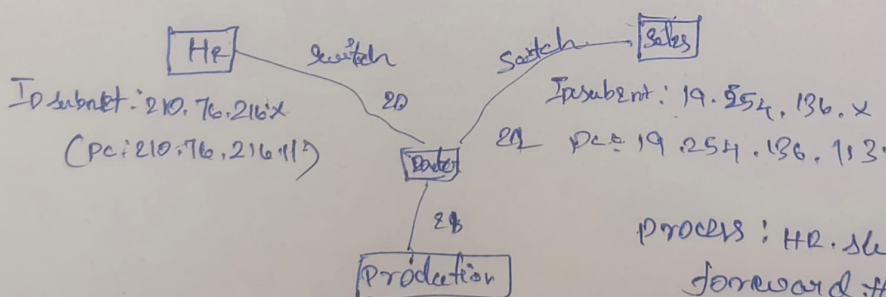

address learning

3, Explain behaviour of router device

Function: connect different network (eg: HR, sales, Production) and breaks broadcast domains using Ip. addressing.

Routing Table: maintain a list of network IDS, Prefixes and Interface to decide where send packets.

Data flow: passes data between network strictly through network

Setup: PC 1 in the HR

(IP: 210.76.216.11)

wants to send data to pc-2 in sales

(IP: 19.254.136.113)

process: HR switch

forward the packet to the router interface
 the check the Routing table.
